## Introduction

`taxlist` is a package designed to handle and assess taxonomic lists in R, providing an object class and functions in S4 language. The homonymous object class `taxlist` was originally designed as a module for taxa recorded in vegetation-plot observations (see [vegtable](#)), but became as an independent object with the ability of contain not only lists of species but also synonymy, hierarchical taxonomy, and functional traits (attributes of taxa).

The main aim of this package is to keep consistence in taxonomic lists (a set of rules are checked by the function `validObject()`), to enable the re-arrangement of such data, and to statistically assess functional traits and other attributes, for instance taxonomy itself (function [tax2traits\(\)](#) set taxonomic information as trait).

While this package only includes a function for the import of taxonomic lists from [Turboveg](#), almost any data source can be structured as `taxlist` object, so far the information is imported into data frames in an R session and the consistency rules are respected (validity).

The use of `taxlist` is recommended for people cleaning raw data before importing it to relational databases, either in the context of taxonomic work or biodiversity assessments. The other way around, people having relational databases or clean and structured taxonomic lists may

- ▶ Each slot is a data frame
- ▶ Consistency checked by `validObject()`

## Target Information

- ▶ Diverse degrees of completeness
- ▶ Any hierarchical taxonomy
  - ▶ Also syntaxonomy

A photograph of a mangrove forest. The scene is framed by large, leafy mangrove trees on both sides. A narrow, dark green waterway or canal cuts through the center. The sky above is filled with heavy, grey clouds.

**Thank You!**

Jesse Fleri, mangrove, Gilligan's Island, Puerto Rico
